

# RAMSEY THEORY

## Ramsey's Theorem

Suppose we 2-colour the edges of  $K_6$  of Red and Blue. There *must* be either a Red triangle or a Blue triangle.

This is not true for  $K_5$ .

There are 3 edges of the same colour incident with vertex 1, say  $(1,2)$ ,  $(1,3)$ ,  $(1,4)$  are Red. Either  $(2,3,4)$  is a blue triangle or one of the edges of  $(2,3,4)$  is Red, say  $(2,3)$ . But the latter implies  $(1,2,3)$  is a Red triangle.

## Ramsey's Theorem

For all positive integers  $k, \ell$  there exists  $R(k, \ell)$  such that if  $N \geq R(k, \ell)$  and the edges of  $K_N$  are coloured Red or Blue then then either there is a “Red  $k$ -clique” or there is a “Blue  $\ell$ -clique. A clique is a complete subgraph and it is Red if all of its edges are coloured red etc.

$$\begin{aligned}R(1, k) &= R(k, 1) = 1 \\R(2, k) &= R(k, 2) = k\end{aligned}$$

## Theorem

$$R(k, l) \leq R(k, l - 1) + R(k - 1, l).$$

**Proof** Let  $N = R(k, l - 1) + R(k - 1, l)$ .

$V_R = \{(x : (1, x) \text{ is coloured Red})\}$  and  $V_B = \{(x : (1, x) \text{ is coloured Blue})\}$ .

$$|V_R| \geq R(k-1, \ell) \text{ or } |V_B| \geq R(k, \ell-1).$$

Since

$$\begin{aligned} |V_R| + |V_B| &= N - 1 \\ &= R(k, \ell - 1) + R(k - 1, \ell) - 1. \end{aligned}$$

Suppose for example that  $|V_R| \geq R(k-1, \ell)$ . Then either  $V_R$  contains a Blue  $\ell$ -clique – done, or it contains a Red  $k-1$ -clique  $K$ . But then  $K \cup \{1\}$  is a Red  $k$ -clique. Similarly, if  $|V_B| \geq R(k, \ell-1)$  then either  $V_B$  contains a Red  $k$ -clique – done, or it contains a Blue  $\ell-1$ -clique  $L$  and then  $L \cup \{1\}$  is a Blue  $\ell$ -clique. □

## Theorem

$$R(k, \ell) \leq \binom{k + \ell - 2}{k - 1}.$$

**Proof** Induction on  $k + \ell$ . True for  $k + \ell \leq 5$  say. Then

$$\begin{aligned} R(k, \ell) &\leq R(k, \ell - 1) + R(k - 1, \ell) \\ &\leq \binom{k + \ell - 3}{k - 1} + \binom{k + \ell - 3}{k - 2} \\ &= \binom{k + \ell - 2}{k - 1}. \end{aligned}$$

□

So, for example,

$$\begin{aligned} R(k, k) &\leq \binom{2k - 2}{k - 1} \\ &\leq 4^k \end{aligned}$$

## Theorem

$$R(k, k) > 2^{k/2}$$

**Proof** We must prove that if  $n \leq 2^{k/2}$  then there exists a Red-Blue colouring of the edges of  $K_n$  which contains no Red  $k$ -clique and no Blue  $k$ -clique. We can assume  $k \geq 4$  since we know  $R(3, 3) = 6$ .

We show that this is true with positive probability in a *random* Red-Blue colouring. So let  $\Omega$  be the set of all Red-Blue edge colourings of  $K_n$  with uniform distribution. Equivalently we independently colour each edge Red with probability  $1/2$  and Blue with probability  $1/2$ .

Let

$\mathcal{E}_R$  be the event: {There is a Red  $k$ -clique} and

$\mathcal{E}_B$  be the event: {There is a Blue  $k$ -clique}.

We show

$$\Pr(\mathcal{E}_R \cup \mathcal{E}_B) < 1.$$

Let  $C_1, C_2, \dots, C_N$ ,  $N = \binom{n}{k}$  be the vertices of the  $N$   $k$ -cliques of  $K_n$ .

Let  $\mathcal{E}_{R,j}$  be the event:  $\{C_j \text{ is Red}\}$  and let  $\mathcal{E}_{B,j}$  be the event:  $\{C_j \text{ is Blue}\}$ .

$$\begin{aligned}
\Pr(\mathcal{E}_R \cup \mathcal{E}_B) &\leq \Pr(\mathcal{E}_R) + \Pr(\mathcal{E}_B) = 2\Pr(\mathcal{E}_R) \\
&= 2\Pr\left(\bigcup_{j=1}^N \mathcal{E}_{R,j}\right) \leq 2\sum_{j=1}^N \Pr(\mathcal{E}_{R,j}) \\
&= 2\sum_{j=1}^N \left(\frac{1}{2}\right)^{\binom{k}{2}} = 2\binom{n}{k} \left(\frac{1}{2}\right)^{\binom{k}{2}} \\
&\leq 2\frac{n^k}{k!} \left(\frac{1}{2}\right)^{\binom{k}{2}} \\
&\leq 2\frac{2^{k^2/2}}{k!} \left(\frac{1}{2}\right)^{\binom{k}{2}} \\
&= \frac{2^{1+k/2}}{k!} \\
&< 1.
\end{aligned}$$

Very few of the Ramsey numbers are known exactly. Here are a few known values.

$$R(3, 3) = 6$$

$$R(3, 4) = 9$$

$$R(4, 4) = 18$$

$$R(4, 5) = 25$$

$$43 \leq R(5, 5) \leq 49$$

# Ramsey's Theorem in general

Remember that the elements of  $\binom{S}{r}$  are the  $r$ -subsets of  $S$

## Theorem

Let  $r, s \geq 1$ ,  $q_i \geq r$ ,  $1 \leq i \leq s$  be given. Then there exists  $N = N(q_1, q_2, \dots, q_s; r)$  with the following property: Suppose that  $S$  is a set with  $n \geq N$  elements. Let each of the elements of  $\binom{S}{r}$  be given one of  $s$  colors. .

Then there exists  $i$  and a  $q_i$ -subset  $T$  of  $S$  such that all of the elements of  $\binom{T}{r}$  are colored with the  $i$ th color.

**Proof** First assume that  $s = 2$  i.e. two colors, Red, Blue.

# Ramsey's Theorem in general

Note that

$$(a) N(p, q; 1) = p + q - 1$$

$$(b) N(p, r; r) = p(\geq r)$$

$$N(r, q; r) = q(\geq r)$$

We proceed by induction on  $r$ . It is true for  $r = 1$  and so assume  $r \geq 2$  and it is true for  $r - 1$  and arbitrary  $p, q$ . Now we further proceed by induction on  $p + q$ . It is true for  $p + q = 2r$  and so assume it is true for  $r$  and all  $p', q'$  with  $p' + q' < p + q$ .

Let

$$p_1 = N(p - 1, q; r)$$

$$p_2 = N(p, q - 1; r)$$

These exist by induction.

# Ramsey's Theorem in general

Now we prove that

$$N(p, q; r) \leq 1 + N(p_1, q_1; r - 1)$$

where the RHS exists by induction.

Suppose that  $n \geq 1 + N(p_1, q_1; r - 1)$  and we color  $\binom{[n]}{r}$  with 2 colors. Call this coloring  $\sigma$ .

From this we define a coloring  $\tau$  of  $\binom{[n-1]}{r-1}$  as follows: If  $X \in \binom{[n-1]}{r-1}$  then give it the color of  $X \cup \{n\}$  under  $\sigma$ .

Now either (i) there exists  $A \subseteq [n-1]$ ,  $|A| = p_1$  such that (under  $\tau$ ) all members of  $\binom{A}{r-1}$  are Red or (ii) there exists  $B \subseteq [n-1]$ ,  $|B| = q_1$  such that (under  $\tau$ ) all members of  $\binom{B}{r-1}$  are Blue.

# Ramsey's Theorem in general

Assume w.l.o.g. that (i) holds.

$$|A| = p_1 = N(p-1, q; r).$$

Then either

(a)  $\exists B \subseteq A$  such that  $|B| = q$  and under  $\sigma$  all of  $\binom{B}{r}$  is Blue,

or

(b)  $\exists A' \subseteq A$  such that  $|A'| = p-1$  and all of  $\binom{A'}{r}$  is Red. But then all of  $\binom{A' \cup \{n\}}{r}$  is Red. If  $X \subseteq A'$ ,  $|X| = r-1$  then  $\tau$  colors  $X$  Red, since  $A' \subseteq A$ . But then  $\sigma$  will color  $X \cup \{n\}$  Red.

# Ramsey's Theorem in general

Now consider the case of  $s$  colors. We show that

$$N(q_1, q_2, \dots, q_s; r) \leq N(Q_1, Q_2; r)$$

where

$$Q_1 = N(q_1, q_2, \dots, q_{\lfloor s/2 \rfloor}; r)$$

$$Q_2 = N(q_{\lfloor s/2 \rfloor + 1}, q_{\lfloor s/2 \rfloor + 2}, \dots, q_s; r)$$

Let  $n = N(Q_1, Q_2; r)$  and assume we are given an  $s$ -coloring of  $\binom{[n]}{r}$ .

First temporarily re-color Red, any  $r$ -set colored with  $i \leq \lfloor s/2 \rfloor$  and re-color Blue any  $r$ -set colored with  $i > \lfloor s/2 \rfloor$ .

# Ramsey's Theorem in general

Then either (a) there exists a  $Q_1$ -subset  $A$  of  $[n]$  with  $\binom{A}{r}$  colored Red or (b) there exists a  $Q_2$ -subset  $B$  of  $[n]$  with  $\binom{B}{r}$  colored Blue.

W.l.o.g. assume the first case. Now replace the colors of the  $r$ -sets of  $A$  by their original colors. We have a  $\lfloor s/2 \rfloor$ -coloring of  $\binom{A}{r}$ . Since  $|A| = N(q_1, q_2, \dots, q_{\lfloor s/2 \rfloor}; r)$  there must exist some  $i \leq \lfloor s/2 \rfloor$  and a  $q_i$ -subset  $S$  of  $A$  such that all of  $\binom{S}{r}$  has color  $i$ .

□

# Hales-Jewett Theorem

The  $n$ -dimensional  $m$ -cube is defined as

$$[m]^n = \{\mathbf{x} = (x_1, x_2, \dots, x_n) : 1 \leq x_i \leq m\}.$$

A subset  $L \subseteq [m]^n$  is a **combinatorial line** if there exists a non-empty set  $I \subseteq [n]$  and integers  $a_i, i \notin I$  such that

$$L = \{\mathbf{x} \in [m]^n : x_i = a_i, i \notin I \text{ and } x_i = x_j \text{ for } i, j \in I\}.$$

For example if  $n = 5, m = 4$  and  $I = \{1, 3, 5\}, a_2 = 3, a_4 = 1$  then

$\{(1, 3, 1, 1, 1), (2, 3, 2, 1, 2), (3, 3, 3, 1, 3), (4, 3, 4, 1, 4)\}$  is a line.

Note that the **active indices** in  $I$  are required to increase from 1 to  $m$ .

# Hales-Jewett Theorem

## Theorem

*For all positive integers  $r, m$  there exists a least integer  $HJ(r, m)$  such that if  $n \geq HJ(r, m)$  and  $[m]^n$  is colored with  $r$  colors, then there is a monochromatic combinatorial line.*

**Proof:** Note that if every  $r$ -coloring of  $[m]^n$  contains a monochromatic line, then so does every  $r$ -coloring of  $[m]^{n+1}$ . (If we fix  $x_{n+1} = 1$  then we are essentially dealing with  $[m]^n$ .)

Given a line  $L$  we define  $L^-, L^+$  to be its first and last points, as the active indices increase from  $1$  to  $m$ .

# Hales-Jewett Theorem

Lines  $L_1, L_2, \dots, L_s$  are **focused** at a point  $f$  if  $L_i^+ = f$  for  $i = 1, 2, \dots, s$ .

Lines  $L_1, L_2, \dots, L_s$  are **color focused** at a point  $f$  if they are focused at  $f$  and the truncated lines  $L_i \setminus \{L_i^+\}$  are monochromatic with different colors.

For the proof we use induction on  $m$ . The case  $m = 1$  is trivial.

We will show by induction on  $s$  that for each  $1 \leq s \leq r$  there exists  $N = FHJ(r, s, m)$  such that any  $r$ -coloring of  $[m]^N$  contains either

- 1 A monochromatic line, or
- 2  $s$  color-focused lines.

# Hales-Jewett Theorem

The case  $s = r$  implies the theorem, since at least one of the foci  $f_i$  of the  $r$  lines has the same color as the common color of the truncated lines and extend it to a whole line.

For  $s = 1$  we take  $FHJ(r, 1, m) = HJ(r, m - 1)$ , which exists by induction. (We just need to add an  $m$ th point to the monochromatic line of length  $m - 1$ .)

Assuming that  $n \stackrel{d}{=} FHJ(r, s - 1, m)$  exists, we claim that

$$FHJ(r, s, m) \leq N = n + n',$$

where  $n' \stackrel{d}{=} HJ(r^{m^n}, m - 1)$ . (Note that the inductive assumption assumes that  $HJ(\rho, m - 1)$  exists for all choices of  $\rho$ .)

# Hales-Jewett Theorem

An  $r$ -coloring  $\chi$  of  $[m]^N = [m]^n \times [m]^{n'}$  can be thought of as an  $r^{m^n}$  coloring  $\chi'$  of  $[m]^{n'}$  where  $b \in [m]^{n'}$  is “colored” with the  $\chi$ -colored cube  $\{(a, b) : a \in [m]^n\}$ .

By induction on  $m$ , there is a line  $L$  in  $[m]^{n'}$  with active coordinate set  $I$  such that the truncated line  $L \setminus \{L^+\}$  is monochromatic. (This being a line in  $[m-1]^{n'}$ .)

In terms of  $\chi$  this means that for all  $a \in [m]^n$  and all  $b, b' \in L \setminus \{L^+\}$ , we have

$$\chi((a, b)) = \chi((a, b')) \stackrel{d}{=} \chi''(a).$$

# Hales-Jewett Theorem

Now we examine  $\chi''$ . By hypothesis, (induction on  $s$ ), either (i) there is a monochromatic line or (ii) we can find  $s - 1$  color focused lines  $L_1, \dots, L_{s-1}$  in  $[m]^n$  with active coordinate sets  $I_1, \dots, I_{s-1}$  and focus  $f$ . Assume that (ii) holds, implying that  $f$  has a different color to  $L_i, i < s$ .

For  $1 \leq i \leq s - 1$ , define  $L'_i$  to be the line in  $[m]^N$  with first point  $(L_i^-, L^-)$  and active coordinates  $I_i \cup I$ ,

Define  $L'_s$  to be the line in  $[m]^N$  with first point  $(f, L^-)$  and active coordinate set  $I$ .

The lines  $L'_i, 1 \leq i \leq s$  form a set of  $s$  color-focused lines with focus  $(f, L^+)$ , completing the induction on  $s$ .

(Note that  $L'_s$  has a different color to  $L'_i, i < s$  because  $f$  has a different color to  $L_i, i < s$ .)

# Van der Waerden's theorem

An *arithmetic progression* is a sequence of integers  $a, a + d, \dots, a + (m - 1)d$  where  $a, d > 0$ . The length of the progression is  $m$ .

## Theorem

*There exists a positive integer  $W = W(m, k)$  such that if  $n \geq W$  and the integers  $[n]$  are colored with  $k$  colors then  $[n]$  contains a monochromatic arithmetic progression of length  $m$ .*

**Proof** Let  $n = HJ(m, k)$ . Let  $n = HJ(m, k)$ . Give  $[mn]$  a  $k$ -coloring  $c : [mn] \rightarrow [k]$  and define  $c' : [m]^n \rightarrow [k]$  by letting  $c'(x_1, x_2, \dots, x_n) := c(x_1 + x_2 + \dots + x_n)$ , for  $x_1, x_2, \dots, x_n \in [m]$ .

Since  $x_1 + x_2 + \dots + x_n \leq mn$ , the function is well-defined. By the definition of  $n$ , there exists a monochromatic line in  $[m]^n$ . Let  $I$  be the set of active coordinates and  $d = |I|$ .

# Van der Waerden's theorem

Let  $a = \sum L^-$ . Note that

$$L^- = \{(x_1, x_2, \dots, x_n) \mid x_i = a_i \text{ for } i \in I \text{ and } x_i = 1, \text{ for } i \notin I\},$$

and the  $j$ th point

$$L^j = \{(x_1, x_2, \dots, x_n) \mid x_i = a_i, \text{ for } i \in I \text{ and } x_i = j, \text{ for } i \notin I\}.$$

This means  $a + (j-1)d = \sum L^j$ . The line is monochromatic and so  $a, a+d, a+(m-1)d$  are colored the same

Thus  $W(m, k) \leq mHJ(m, k)$ .

# Schur's Theorem

Let  $r_k = N(3, 3, \dots, 3; 2)$  be the smallest  $n$  such that if we  $k$ -color the edges of  $K_n$  then there is a mono-chromatic triangle.

## Theorem

*For all partitions  $S_1, S_2, \dots, S_k$  of  $[r_k]$ , there exist  $i$  and  $x, y, z \in S_i$  such that  $x + y = z$ .*

**Proof** Given a partition  $S_1, S_2, \dots, S_k$  of  $[n]$  where  $n \geq r_k$  we define a coloring of the edges of  $K_n$  by coloring  $(u, v)$  with color  $j$  where  $|u - v| \in S_j$ .

There will be a mono-chromatic triangle i.e. there exist  $j$  and  $x < y < z$  such that  $u = y - x$ ,  $v = z - x$ ,  $w = z - y \in S_j$ .  
But  $u + v = w$ . □

# Convex Polygons

A set of points  $X$  in the plane is in **general position** if no 3 points of  $X$  are collinear.

## Theorem

*If  $n \geq N(k, k; 3)$  and  $X$  is a set of  $n$  points in the plane which are in general position then  $X$  contains a  $k$ -subset  $Y$  which form the vertices of a convex polygon.*

**Proof** We first observe that if **every** 4-subset of  $Y \subseteq X$  forms a convex quadrilateral then  $Y$  itself induces a convex polygon.

Now label the points in  $S$  from  $X_1$  to  $X_n$  and then color each triangle  $T = \{X_i, X_j, X_k\}$ ,  $i < j < k$  as follows: If traversing triangle  $X_i X_j X_k$  in this order goes round it clockwise, color  $T$  Red, otherwise color  $T$  Blue.

# Convex Polygons

Now there must exist a  $k$ -set  $T$  such that all triangles formed from  $T$  have the same color. All we have to show is that  $T$  does not contain the following configuration:

# Convex Polygons

Assume w.l.o.g. that  $a < b < c$  which implies that  $X_i X_j X_k$  is colored Blue.

All triangles in the previous picture are colored Blue.

So the possibilities are

and all are impossible.

# Ramsey $R(H_1, H_2)$

We define  $r(H_1, H_2)$  to be the minimum  $n$  such that in in Red-Blue coloring of the edges of  $K_n$  there is either (i) a Red copy of  $H_1$  or (ii) a Blue copy of  $H_2$ .

As an example, consider  $r(P_3, P_3)$  where  $P_t$  denotes a path with  $t$  edges.

We show that

$$r(P_3, P_3) = 5.$$

$R(P_3, P_3) > 4$ : We color edges incident with 1 Red and the remaining edges  $\{(2, 3), (3, 4), (4, 1)\}$  Blue. There is no mono-chromatic  $P_3$ .

# Ramsey $R(H_1, H_2)$

$R(P_3, P_3) \leq 5$ : There must be two edges of the same color incident with 1.

Assume then that  $(1, 2), (1, 3)$  are both Red.

If any of  $(2, 4), (2, 5), (3, 4), (3, 5)$  are Red then we have a Red  $P_3$ .

If all four of these edges are Blue then  $(4, 2, 5, 3)$  is Blue.

# Ramsey $R(H_1, H_2)$

We show next that  $r(K_{1,s}, P_t) \leq s + t$ . Here  $K_{1,s}$  is a **star**: i.e. a vertex  $v$  and  $t$  incident edges.

Let  $n = s + t$ . If there is no vertex of Red degree  $s$  then the minimum degree in the graph induced by the Blue edges is at least  $t$ .

We then note that a graph of minimum degree  $\delta$  contains a path of length  $\delta$ .
