B-I. Polynomials

Po-Shen Loh

14 June 2004

1 Warm-Ups

1. Consider the cubic equation $ax^3 + bx^2 + cx + d = 0$. The roots are

$$x = \sqrt[3]{\left(\frac{-b^3}{27a^3} + \frac{bc}{6a^2} - \frac{d}{2a}\right)} + \sqrt{\left(\frac{-b^3}{27a^3} + \frac{bc}{6a^2} - \frac{d}{2a}\right)^2 + \left(\frac{c}{3a} - \frac{b^2}{9a^2}\right)^3} + \sqrt[3]{\left(\frac{-b^3}{27a^3} + \frac{bc}{6a^2} - \frac{d}{2a}\right)} - \sqrt{\left(\frac{-b^3}{27a^3} + \frac{bc}{6a^2} - \frac{d}{2a}\right)^2 + \left(\frac{c}{3a} - \frac{b^2}{9a^2}\right)^3} - \frac{b}{3a}.$$

Prove that no such general formula exists for a quintic equation.

2 Theory

Thanks to Elgin Johnston (1997) for these theorems.

- **Rational Root Theorem** Let $p(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_0$ be a polynomial with integer coefficients. Then any rational solution r/s (expressed in lowest terms) must have $r|a_0$ and $s|a_n$.
- **Descartes's Rule of Signs** Let $p(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_0$ be a polynomial with real coefficients. Then the number of positive roots is equal to N - 2k, where N is the number of sign changes in the coefficient list (ignoring zeros), and k is some nonnegative integer.
- **Eisenstein's Irreducibility Criterion** Let $p(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_0$ be a polynomial with integer coefficients and let q be a prime. If q is a factor of each of $a_{n-1}, a_{n-2}, \ldots, a_0$, but q is not a factor of a_n , and q^2 is not a factor of a_0 , then p(x) is irreducible over the rationals.
- Einstein's Theory of Relativity Unfortunately, this topic is beyond the scope of this program.
- **Gauss's Theorem** If p(x) has integer coefficients and p(x) can be factored over the rationals, then p(x) can be factored over the integers.
- **Lagrange Interpolation** Suppose we want a degree-*n* polynomial that passes through a set of n+1 points: $\{(x_i, y_i)\}_{i=0}^n$. Then the polynomial is:

$$p(x) = \sum_{i=0}^{n} \frac{y_i}{\text{normalization}} (x - x_0)(x - x_1) \cdots (x - x_n),$$

where the *i*-th "normalization" factor is the product of all the terms $(x_i - x_j)$ that have $j \neq i$.

3 Problems

Thanks to Elgin Johnston (1997) for most of these problems.

- 1. (Crux Math., June/July 1978) Show that $n^4 20n^2 + 4$ is composite when n is any integer. Solution: Factor as difference of two squares. Prove that neither factor can be ± 1 .
- 2. (St. Petersburg City Math Olympiad 1998/14) Find all polynomials P(x, y) in two variables such that for any x and y, P(x + y, y x) = P(x, y).

Solution: Clearly constant polynomials work. Also, P(x, y) = P(x + y, y - x) = P(2y, -2x) = P(16x, 16y). Suppose we have a nontrivial polynomial. Then on the unit circle, it is bounded because we can just look at the fixed coefficients. Yet along each ray y = tx, we get a polynomial whose translate has infinitely many zeros, so it must be constant. Hence P is constant along all rays, implying that P is bounded by its max on the unit circle, hence bounded everywhere. Now suppose maximum degree of y is N. Study the polynomial $P(z^{N+1}, z)$. The leading coeff of this is equal to the leading coeff of P(x, y) when sorted with respect to x as more important. Since the z-poly is also bounded everywhere, it too must be constant, implying that the leading term is a constant.

3. (Putnam, May 1977) Determine all solutions of the system

$$\begin{aligned} x+y+z &= w\\ \frac{1}{x}+\frac{1}{y}+\frac{1}{z} &= \frac{1}{w}. \end{aligned}$$

Solution: Given solutions x, y, z, construct 3-degree polynomial P(t) = (t - x)(t - y)(t - z). Then $P(t) = t^3 - wt^2 + At - Aw = (t^2 + A)(t - w)$. In particular, roots are w and a pair of opposites.

4. (Crux Math., April 1979) Determine the triples of integers (x, y, z) satisfying the equation

$$x^{3} + y^{3} + z^{3} = (x + y + z)^{3}.$$

Solution: Move z^3 to RHS and factor as $x^3 \pm y^3$. We get (x + y) = 0 or (y + z)(z + x) = 0. So two are opposites.

5. (USSR Olympiad) Prove that the fraction $(n^3 + 2n)/(n^4 + 3n^2 + 1)$ is in lowest terms for every positive integer n.

Solution: Use Euclidean algorithm for GCD. $(n^3 + 2n)n = n^4 + 2n^2$, so difference to denominator is $n^2 + 1$. Yet that's relatively prime to $n(n^2 + 2)$.

- 6. (Po, 2004) Prove that $x^4 x^3 3x^2 + 5x + 1$ is irreducible. Solution: Eisenstein with substitution $x \mapsto x + 1$.
- 7. (Canadian Olympiad, 1970) Let P(x) be a polynomial with integral coefficients. Suppose there exist four distinct integers a, b, c, d with P(a) = P(b) = P(c) = P(d) = 5. Prove that there is no integer k with P(k) = 8.

Solution: Drop it down to 4 zeros, and check whether one value can be 3. Factor as P(x) = (x-a)(x-b)(x-c)(x-d)R(x); then substitute k. 3 is prime, but we'll get at most two ±1 terms from the $(x-\alpha)$ product.

8. (Monthly, October 1962) Prove that every polynomial over the complex numbers has a nonzero polynomial multiple whose exponents are all divisible by 10⁹.

Solution: Factor polynomial as $a(x - r_1)(x - r_2) \cdots (x - r_n)$. Then the desired polynomial is $a(x^P - r_1^P) \cdots (x^P - r_n^P)$, where $P = 10^9$. Each factor divides the corresponding factor.

9. (Elgin, MOP 1997) For which n is the polynomial $1 + x^2 + x^4 + \dots + x^{2n-2}$ divisible by the polynomial $1 + x + x^2 + \dots + x^{n-1}$?

Solution: Observe:

$$\begin{aligned} &(x^2-1)(1+x^2+x^4+\dots+x^{2n-2}) &= x^{2n}-1\\ &(x-1)(1+x+x^2+\dots+x^{n-1}) &= x^n-1\\ &(x+1)(1+x^2+x^4+\dots+x^{2n-2}) &= (x^n+1)(1+x+x^2+\dots+x^{n-1}) \end{aligned}$$

So if the quotient is Q(x), then $Q(x)(x+1) = x^n + 1$. This happens iff -1 is a root of $x^n + 1$, which is iff n is odd.

10. (Czech-Slovak Match, 1998/1) A polynomial P(x) of degree $n \ge 5$ with integer coefficients and n distinct integer roots is given. Find all integer roots of P(P(x)) given that 0 is a root of P(x).

Solution: Answer: just the roots of P(x). Proof: write $P(x) = x(x-r_1)(x-r_2)\cdots(x-r_N)$. Suppose we have another integer root r; then $r(r-r_1)\cdots(r-r_N) = r_k$ for some k. Since degree is at least 5, this means that we have $2r(r-r_k)$ dividing r_k . Simple analysis shows that r is between 0 and r_k ; more analysis shows that we just need to defuse the case of $2ab \mid a + b$. Assume $a \leq b$. Now if a = 1, only solution is b = 1, but then we already used ± 1 in the factors, so we actually have to have $12r(r-r_k)$ dividing r_k , no good. If a > 1, then $2ab > 2b \geq a + b$, contradiction.

11. (Hungarian Olympiad, 1899) Let r and s be the roots of

$$x^{2} - (a+d)x + (ad-bc) = 0.$$

Prove that r^3 and s^3 are the roots of

$$y^{2} - (a^{3} + d^{3} + 3abc + 3bcd)y + (ad - bc)^{3} = 0.$$

Hint: use Linear Algebra.

Solution: r and s are the eigenvalues of the matrix

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

The y equation is the characteristic polynomial of the cube of that matrix.

12. (Hungarian Olympiad, 1981) Show that there is only one natural number n such that $2^8 + 2^{11} + 2^n$ is a perfect square.

Solution: $2^8 + 2^{11} = 48^2$. So, need to have 2^n as difference of squares $N^2 - 48^2$. Hence (N + 48), (N - 48) are both powers of 2. Their difference is 96. Difference between two powers of 2 is of the form $2^M(2^N - 1)$. Uniquely set to $2^7 - 2^5$.

- 13. (MOP 97/9/3) Let $S = \{s_1, s_2, \ldots, s_n\}$ be a set of *n* distinct complex numbers, for some $n \ge 9$, exactly n-3 of which are real. Prove that there are at most two quadratic polynomials f(z) with complex coefficients such that f(S) = S (that is, *f* permutes the elements of *S*).
- 14. (MOP 97/9/1) Let $P(x) = a_0 x^n + a_1 x^{n-1} + \dots + a_n$ be a nonzero polynomial with integer coefficients such that P(r) = P(s) = 0 for some integers r and s, with 0 < r < s. Prove that $a_k \leq -s$ for some k.
